TechTalk #77
Digital-ATV – Testing Report – Part 1
by Ken W6HHC
&
Robbie KB6CJZ

In the May 2009 OCARC newsletter, TechTalk presented an introduction to D-ATV. In the June newsletter, Robbie-KB6CJZ and I teamed-up to present a top-down approach for planning a DATV Station that resulted in selecting the DVB-S standard. The July TechTalk explained how Symbol-rate and FEC affected the RF Bandwidth on DVB-S. In this article, Robbie and I team up to test and share the initial test results of the DATV station we had planned.

Configuring the DATV Transmitter
A “breadboard” for testing the DATV transmitter for the DVB-S standard is shown in Fig 1. These boards were purchased from SR-Systems located in Germany (...see links at the end). Fig 2 shows a block diagram of the entire DATV station and how the two boards fit into the station. Note that we have not yet added an RF power amplifier to the test set up, so we tested with only 1 mW output on 1.290 GHz.

Choosing the transmitter frequency and all other set-ups and adjustments with the DVB-S transmitter and the MPEG2 compressor are made through an RS232 interface connected on the DVB-S Exciter board. I used a RS232-to-USB adapter to plug the RS232 cable into the notebook computer. By running a WindowsXP application called “Hyper-Terminal”, I can read out the settings on the boards and make changes to the settings. Fig 3 is a typical display of the settings menu as seen on the notebook computer.

DVB MiniMod Firmware V54.34 LOWDVBT
(c) 2009 maintech GmbH
OnBoard VCO: ADF4360-0
Real HF output range from 575000 to 1425000 kHz.
FPGA firmware v042.
Encoder firmware upload done (tp5146, 0x01600425).

MiniMod Mainmenu
1) show status
2) Input Settings
3) Modulation Settings
4) Video Settings
5) Audio Settings
6) PSI Settings
7) PID Settings
> 3

Modulation Settings
1) TX Enable (ON AIR)
2) Output Frequency (1290000 kHz)
3) Spectrum (normal)
4) Carrier Only (no)
5) Output Gain (12)
6) Symbolrate (2500 ksym/s)
7) Coderate (FEC) (3/4)
0) exit menu

Figure 2 – Block Diagram Showing DATV Station being Tested

Figure 3 – Typical Hyper-Terminal Menu Display of the DVB-S XMTR Settings
TechTalk – DAVT cont’d from pg 8

Fig 5 also shows how the configuration menu looks like on the notebook computer when no DATV pictures are being displayed. For the test set-up, a very simple ¼ wavelength wire was inserted into the RF SMA connector and used to provide a 1.2 GHz vertical antenna on the XMTR, as shown in Fig 4.

Figure 4 – Simple ¼-wave Vertical Antenna used for Testing the DVB-S Exciter

I used my trusty Kenwood TM-741A FM receiver to confirm that there was a nice strong RF signal centered around 1.290 GHz when the DVB-S exciter was turned on.

Configuring the DATV Receiver

The heart of the DATV receiving station is a ViewSat Model VS2000 Xtreme DVB-S SetTopBox (aka FTA or Free-to-Air) that I bought used on e-Bay. The price was right; less than $75, including cost of shipping.

As the block diagram in Fig 2 shows, the output of the STB sends Composite Video to the USB port on the Dell notebook computer via Composite-Video-to-USB converter that costs about $50 on the internet. I bought a Startech.com USB 2.0 converter (new) via Amazon. Fig 6 shows a photo of the Startech.com USB 2.0 converter. Note that this model does not send the audio to the computer, only composite-video or S-video. The Startech.com product is primarily designed to capture video files to a disk on a computer and to take “snap shots” of video streams. It includes a software program called GrabBee that...

See TechTalk – cont’d on Page 10

Figure 5 – Photo of the Entire DATV Station – Satellite STB receiver is on right, Notebook for configuring Transmitter in the middle, and DVB-S Transmitter on left.

[Image of Entire DATV Station]
allows the USB data to be displayed on the computer screen. The computer screens in Fig 7 and Fig 8 are being displayed by the GrabBee application software and device drivers.

The hardest part of our first testing session was to determine how to use the SetTopBox receiver to tune in the frequency we wanted, 1.290 GHz. This was not easy. Robbie determined from inspecting the STB menus that the STB local oscillator was 10,600 MHz. So, on this particular brand of STB:

\[ \text{STB Search Freq} = \text{XMIT Freq} + 10,600 \text{ MHz} \]
\[ \text{STB Search Freq} = 1290 \text{ MHz} + 10,600 \text{ MHz} \]
\[ \text{STB Search Freq} = 11890 \text{ MHz} \]

Because each brand of STB has a different user’s interface...we could never determine how to command our STB to search-and-find our signal on a frequency of 11,890 MHz. So we tried a different approach and added a “new transponder” to the GALAXY 10R Satellite settings already on the STB. Now we could edit the frequency for the new transponder to 11890. Fig 7 shows the settings for new ‘transponder 33” is configured to 11890 with a Symbol-Rate (S/R) of 2500 (Ks/sec).

First DATV Test Pictures Received
Once we determined how to correctly configure a “transponder” setting for our frequency on the STB, the picture magically appeared on the notebook screen....crystal clear!! A photo of our first test pictures is shown in Fig 8. To add a little professional touch to the received pictures, Robbie-KB6CJZ inserted his text generator in series with the video input to the MPEG2 encoder board. You can see “W6HHC ORANGE” show up in the upper-left corner of the DATV picture in Fig 8.

The first thing that we noticed was that the audio had very little latency (delay) from real time. Probably about 1 second. For the first test trial, we had set the Symbol-Rate on the transmitter menu to 2.5 Msymb/sec and the MPEG2 data-bit-rate setting to “MANUAL” and 2.5 Mbits/sec, while FEC was set to 3/4. There was noticeable latency in the picture motion and also a noticeable “jerking” to the motion. We were confused to understand what was going on?? Why were we seeing so much video motion jerking??

The answer appeared with a little more testing at higher Symbol-rates. When the GrabBee software was set for default 720 pixel wide picture, the jerking was gone. When the Grab-Bee was set for a 1024 pixel wide picture (full screen), the jerking was extreme. The settings on the transmitter were NOT incorrect, but the receiving notebook computer and its display lacked the processing speed to convert the NTSC video pixels into a full display screen at 1024 pixels wide at the frame rate. The notebook computer was probably dropping five frames (or more?) to process one frame at 1024!!

See TechTalk – cont’d on following Page
Inspecting RF Bandwidth
Robbie used a HP Model 8559A Spectrum Analyzer 0.01-to-21 GHz plug-in (installed in a HP 182T display) to determine the quality of the transmitted QPSK RF signals.

The spectrum analyzer was set to 1.290 GHz - not centered, @500 KHz per /div (horizontal) and a bandwidth at 30 KHz. RF input was set at 0 dB with a two inch sniffer. Robbie checked the signals bandwidth which was reading about 3.5 MHz.

The earlier TechTalk#76 article explained that bandwidth for QPSK (DVB-S) is predicted as:

\[
\text{RF Bandwidth} = 1.33 \times \text{Symbol-Rate} \\
\text{RF Bandwidth} = 1.33 \times 2.5 \text{ Msymbols/sec} \\
\text{RF Bandwidth} = 3.33 \text{ MHz signal}
\]

So our measured bandwidth looked as expected. The signal looked clean and did not drop out when the video was removed. No out-of-band testing or other testing was performed. More test reports will come in later OCARC TechTalk articles.

Findings and Plans
The DATV station works like we had hoped it would work. The picture really is crystal clear. But, we need to still better understand computer display-density processing limitations when displaying DATV video.

We will do more testing at various Symbol-rates and data-bit-rates. Then as a next step, we plan to amplify the RF output from 1 mW to around 10 W. Then we will do some cross-town distance testing.
